

GROUP ACTIVITY · STEPS 1 – 4

AI Across Industries

Where commercial AI actually shows up — and what changes in the business because it exists.

Music Industry

Marketing

Software Development

Roles

Facilitator · Timekeeper · Notetaker · Reporter

1 Connections — what we've each seen

One tool per person. For each: what is it · what industry uses it · what problem it solves · have you used it · what value it provides.

Canva

MARKETING

Generate and design marketing materials used by graphic designer, Youtubers or Ad agency

Problem: Easy of access to supply marketing materials and idea generation instead of using a Ad agency for Millions of dollars

Value: Improve customer experience, save time and increase profit

GitHub Copilot / Claude

SOFTWARE DEVELOPMENT

Writes, explains, and tests code inside the editor.

Problem: Long hours for Design, Development and Testing and Bug fixes

Value: more shipped per developer and efficient cross team collaboration

Suno.ai

Music Industry

popular generative artificial intelligence platform that creates complete, original song including vocals, instrumentation, and lyric from simple text prompts in under a minute.

Value: Youtubers can use to create background songs, Snippets and fusion of genre

Swap in whatever the group actually uses — the four fields matter more than the four names.

2

Concepts — sorting, and what makes AI valuable

Where our examples land

- **Marketing : Canva**
- **Software Development** GitHub Copilot, Claude
- **Music industry : Suno AI**

What makes an AI application commercially valuable?

Cost reduction

Increased productivity

Faster decision-making

Better predictions

Automation

Improved CX

Revenue growth

Risk reduction

Highlighted = the three our examples hit hardest

Our working test: value appears when AI turns a scarce human input into an abundant one — tutor time, copywriting judgment, engineering hours.

3 Music Industry

Suno AI

What does it do? Turns a text prompt into a complete song — lyrics, vocals, instruments, and mixing — in about a minute. You describe a style and a mood, and it produces finished audio. No instrument, no studio, no singer needed.

Business problem? Making music has always required either skill or money. Most people who need a song — a small business making an ad, a game developer, someone posting a video — can't play anything and can't afford to hire a musician or license a track. Stock music libraries are the usual workaround, but the results are generic and never quite fit.

Process it changes? Music creation moves from a skilled craft to a prompt-and-revise loop. The bottleneck shifts from "can you play" to "can you describe what you want." Someone who used to spend two weeks and a studio budget now iterates through twenty versions in an afternoon and picks one.

Decision-making? Taste replaces technique. The human choice becomes selecting and steering rather than performing. On the business side, the platform's decisions about what styles and voices it will generate — and which it blocks — quietly shape what kinds of music get made at scale.

Who benefits? Non-musicians get music they could never have made or afforded. Content creators get cheap, custom, licensable tracks. Suno gets subscription revenue from people who were never in the music market before. Professional musicians and session players lose the low-end commercial work — jingles, background beds, stock tracks.

KEY NUMBER

\$125M

raised by Suno in 2024 at a reported \$500M valuation, less than two years after launch — investors betting that music creation becomes a consumer product, not a professional one.

FUTURE POTENTIAL

Full production tools — stem separation, editing, licensed voice models, and integration into video and game workflows. The bottleneck moves from "can the model make good music" to who owns the training data and who gets paid. That's a legal and licensing problem, not an AI one.

3 Marketing

Canva -AI

What does it do? Generates marketing language — emails, banners, checkout copy — and predicts which wording will convert before anything is sent. Trained on data from roughly 150 million U.S. consumers and 800,000+ structured language experiments.

Business problem? Copy is written on intuition and evaluated after the fact. Classic A/B testing is slow, tests two options, and can't personalize to a segment of one.

Process it changes? Copywriting shifts from write → launch → measure, to generate → predict → personalize in real time. The creative brief becomes a data input.

Decision-making? Word choice arrives with a predicted lift attached, so it stops being an opinion debate between the brand team and the growth team.

Who benefits? Marketing teams (fewer dead campaigns), revenue owners (measurable lift), customers (messaging that reads less like a form letter).

KEY NUMBER

3–5%

increase in online cart conversion / ecommerce revenue reported for Canva Dynamic Motivation.

FUTURE POTENTIAL

Real-time personalized language at every touchpoint. As generation gets commoditized, the defensible asset becomes the outcome data and the brand-safety guardrails — not the model.

3

Software Development

GitHub Copilot/ Claude — AI pair programmer

What does it do? Completes lines and whole functions in the editor, writes tests, explains unfamiliar code, and in agent mode opens pull requests on its own.

Business problem? A large share of engineering time goes to boilerplate, syntax lookups and context switching rather than design and problem-solving.

Process it changes? The job moves from writing code to reviewing and directing generated code. Review and testing become the new bottleneck — and the scarce skill.

Decision-making? Cheaper iteration means more experiments per sprint, and managers reallocate headcount toward architecture and review instead of implementation.

Who benefits? Developers (less drudgery, higher reported job satisfaction), engineering managers (throughput without headcount), the business (faster time to market).

KEY NUMBER

55%

faster task completion in GitHub's controlled study (n=88). In Accenture's enterprise trial: +8.7% pull requests per developer, +15% merge rate.

FUTURE POTENTIAL

Agents that take a ticket end to end. The open question is whether lab speed-ups survive contact with real codebases — several field studies find far smaller aggregate gains.

Source: The GitHub Blog: developer productivity study (n=88) and the GitHub–Accenture enterprise study.

What changes in the business because this AI exists?

The worksheet's most important question — answered as a before and after.

Music Industry

Suno AI

BEFORE

Creating music required musical knowledge, instruments, and significant time for composing and recording.

AFTER

Suno can generate songs, melodies, lyrics, and vocals from a simple text prompt.

MARKETING

Canva

BEFORE

Marketing teams have to spend time design and coming up with moodboard, content that would draw in the customer

AFTER

- AI can generate designs, images, text, and content from simple prompts.
- Marketing materials can be created **faster and with less manual effort.**

SOFTWARE DEVELOPMENT

GitHub Copilot

BEFORE

Capacity scales with headcount; a large slice of that headcount writes boilerplate.

AFTER

Capacity scales with review throughput. Hiring shifts toward people who can judge code, not just produce it.

If you can't name the after, the tool is a demo — not a commercial AI application.

4

Conclusion — the reporter's three lines

MUSIC INDUSTRY

Suno AI makes music creation **quick, easy, and accessible to everyone**. It allows users to create songs with lyrics, melodies, and vocals using simple prompts, even without professional music skills.

MARKETING

In the **marketing** industry, Canva is using AI to **generate copy and predict which wording will convert before a campaign ships**. The most important business impact is **that copy moves from opinion to measured revenue**

SOFTWARE DEVELOPMENT

In the **software development** industry, **GitHub** is using AI to **write, test and explain code alongside developers**. The most important business impact is **that engineering capacity grows without headcount — and the scarce skill shifts from writing code to reviewing it**.
